

Break log — where it breaks, fixed vs. known limitation

Method: the local file was verified to exactly match the live deployed content at <https://jyot-tipsoc.github.io/jyotsana-portfolio/> (fetched and compared directly) before any testing, then genuinely broken with real edge-case scripted tests — empty submission, garbage input, JS disabled entirely, rapid double-click, and a real cold web search for the site.

Fix-now (found, and fixed)

1. The form failed unsafely with JavaScript disabled — real bug

The `<form>` had no `action` or `method` attribute; it relied entirely on JavaScript to intercept submission. Testing with JavaScript disabled (simulating a locked-down or unusual browser) showed the real failure: clicking "Send message" did **not** show an error or do nothing quietly — it reloaded the page with the visitor's name, email, and full message dumped as plain text into the URL bar, and the message was never actually sent anywhere. That's both a data-loss bug (the message is lost) and a privacy problem (message content ends up visible in browser history/URL).

Fix: added `action="https://api.web3forms.com/submit"` `method="POST"` directly on the form tag, plus a hidden `redirect` field pointing back to the site's contact section. Now: JavaScript present → smooth inline success message (unchanged from before); JavaScript absent → the form still natively POSTs to Web3Forms and the visitor lands back on the site, instead of silently failing.

2. No social-share preview (missing Open Graph / Twitter Card tags)

The page had a title and meta description, but nothing else — sharing the link on LinkedIn, Slack, or elsewhere would show a blank or broken preview card, undermining the exact audience (hiring managers) the site is built for.

Fix: added `og:title`, `og:description`, `og:url`, `og:image`, and matching `twitter:card` tags. Also generated a real 1200×630 preview image (`social-preview.png`) in the identity kit's style, rather than pointing the tag at an image that didn't exist — a broken `og:image` would have been its own bug.

Tested and held up (not broken)

- **Empty submission:** browser-native validation correctly blocks it — required fields are flagged, form doesn't submit.
- **Garbage email format** (e.g. `not-an-email`): correctly rejected by the browser's built-in email validation before it ever reaches the network.
- **Rapid double-click:** the submit button is disabled synchronously before the network request starts, so a fast double-click can't fire two submissions.
- **GitHub link:** verified live and resolving correctly.
- `#contact` **anchor link:** native browser anchor scrolling, works with or without JavaScript.

Known limitations (named, not fixed — and why)

- **A genuinely garbage-but-valid-looking email** (e.g. `asdf@asdf.com`) will pass client-side validation and submit successfully — there's no way to verify real ownership of an email address from a static site without a verification-email step, which is out of scope for a simple contact form. This is standard behavior for virtually every contact form on the web, not a defect specific to this build.
- **LinkedIn link could not be automatically verified** — LinkedIn blocks automated fetching of its pages, so this needs a manual click to confirm. (Flagged, not silently skipped.)
- **The résumé button is intentionally disabled** ("coming soon") since no résumé is hosted yet. This is working as designed, not a bug — it was a deliberate honest placeholder rather than a broken or fake link.
- **The site is not yet findable via a real Google search.** Searching "Jyotsana AI-assisted cybersecurity portfolio" just now returned unrelated results — other people named Jyotsana, generic cybersecurity-portfolio articles, nothing pointing to this site. This is expected for a brand-new page (search engines take days to weeks to crawl and index new sites, especially with no existing backlinks) and is not something fixable today. Next steps once traffic/backlinks exist: submit the URL to Google Search Console, and confirm it's linked from LinkedIn/GitHub profiles (already done per PF-04) to help discovery.
- **Speed was not run through an official Lighthouse/PageSpeed audit from my side** — I don't have a tool that can run that against a live URL. What I can confirm: the page is 14 KB of HTML, no JavaScript framework, no images loaded on the initial page render (the social-preview image is only fetched by link-preview crawlers, not by visitors), and the only external requests are Google Fonts. This should score well, but the official number needs to come from a real run — see next step below.

Still to do on your end

1. **Run the real speed check:** go to [PageSpeed Insights](#) and enter your live URL. Screenshot the score as your evidence for the "speed checked" requirement.
2. **Manually click the LinkedIn link** on the live site to confirm it resolves correctly.
3. **Push the fixed `index.html`, plus the new `social-preview.png`**, to your repo root (the image needs to sit alongside `index.html` for the `og:image` URL to resolve).

4. **After redeploying, test a real share preview** — paste your live URL into a LinkedIn post draft (don't publish) or use a tool like opengraph.xyz to confirm the preview card renders correctly, then submit this log for hardening review.
